Q1 a) Consider the example from the question:

| src | tgt | weight |
|-----|-----|--------|
| 117 | 51 | 1 |
| 194 | 51 | 1 |
| 299 | 51 | 3 |
| 230 | 151 | 51 |
| 194 | 151 | 79 |
| 51 | 130 | 10 |

This is the input to the MAP function. To illustrate, in the first iteration, we have 117 51 1. This is converted to a string and split at the tab space. We map the target node to the weight such that output of the MAP function will be:

| KEY | VALUE |
|-----|-------|
| 51 | 1 |
| 51 | 1 |
| 51 | 3 |
| 151 | 51 |
| 151 | 79 |
| 130 | 10 |

This is the input to the Reducer function. The reducer function combines all values from the same KEY. Our reducer function specifically reduces entries with same KEY to one entry and maps it to the maximum VALUE for that KEY. The output of the reducer function will be,

| KEY | VALUE |
|-----|-------|
| 51 | 3 |
| 151 | 79 |
| 130 | 10 |

Q1 b)

Step 1: In java, divide the single dataset(inputFile) into separate datasets for Student records (<Department_ID, Name>) and Department records (<Department_ID, Department_Name>). This is the input to the Map phase.

| STUDENT | DEPARTMENT |
|-----------------------|----------------------------------|
| [Department_ID, Name] | [Department_ID, Department_Name] |
| 1234, Alice | 1123, CSE |
| 1234, Bob | 1234, CS |
| 1123, Joe | |

Step 2: Create a custom writable (TaggedKey class in the article). The map output key will be a composite key that will belong to this class.

Step 3: The composite key is made up of the join key (in this case Department_ID) and an attribute 'tag' which tags the identity of the data (1=name, 2=department name).

| STUDENT | DEPARTMENT |
|------------------------------------|-----------------------------------|
| Composite key: [Department_ID, 1], | Composite key: [Department_ID, 2] |
| Value: [Name] | Value: [Department_Name] |
| [1234, 1], Alice | [1123, 2], CSE |
| [1234, 1], Bob | [1234, 2], CS |
| [1123, 1], Joe | |

Step 3: Partition the data on key Department_ID by creating a custom partitioner class.

Step 4: Create a custom sorting comparator class to sort data first on Department_ID and then on tag.

Step 5: Group data based on natural key using custom grouping comparator class. Input to reducer class:

| KEY | VALUE |
|-----------------|----------------------------|
| [Department_ID] | {[Name],[Department_Name]} |
| 1123 | [Joe, CSE] |
| 1234 | [Alice, CS] |
| 1234 | [Bob, CSE] |

Step 6: Iterate through the values for a key(Department_ID) and complete the join for student Name and Department Name. Output of reducer is of the form:

| 1123, Joe, CSE | |
|-----------------|--|
| 1234, Alice, CS | |
| 1234, Bob, CS | |
